

SIH 2026 — Team Role Allocation

Combined Solution: SIH26092 + SIH26129

Problem Statement : 26129

Project Focus

A single platform for entrepreneurs that helps them find suitable government schemes, check eligibility, start applications, and track related services through one interface. The project uses an interoperability layer to connect different service systems without replacing the systems themselves.

Member	Role	What this person will mainly do
Shivam	Backend + Interoperability	Build the server and APIs. Connect the different service modules, handle login/authentication, move data between systems, and create the common application-status/tracking layer.
Vanshika	Research + Problem Validation	Study existing government platforms and similar products. Find what already exists, what is missing, and collect reliable evidence to support our problem, solution and USP.
Vartika	Scheme Intelligence	Create the scheme database and rules. Decide whether a user is eligible and which schemes match the user's profile, including reasons and missing requirements.
Swati	Product + Coordination	Define what the product should do, create the complete user journey, prioritize features for the MVP, coordinate dependencies, and maintain requirements and presentation flow.
Zain	AI + Innovation	Work on useful AI features such as natural-language scheme search, extracting user requirements from queries, semantic matching, and identifying meaningful innovations for the project.
Shubhi	Frontend + UI/UX	Build the website screens and user experience: onboarding, dashboard, scheme results, application tracking and other pages. Connect the frontend to the backend APIs.

Detailed Responsibilities with Simple Examples

Shivam — Backend + Interoperability

- Build the Node.js/Express backend and REST APIs.
- Handle login, authentication, validation and backend errors.
- Create the middle layer that allows different service systems to communicate using a common format.
- Map different field names into one common format. Example: one system uses “full_name” while another uses “applicantName”; our platform stores both as “name”.
- Create APIs for application status and unified tracking.
- Coordinate API contracts with the frontend, scheme engine and AI module.

Vanshika — Research + Problem Validation

- Research API Setu, NAPIX, UMANG, DigiLocker, myScheme and relevant entrepreneurship platforms.
- For each existing solution, record what it does, what it does not do, and where our proposed solution can add value.
- Research the actual entrepreneur journey and identify repeated data entry, fragmented tracking and other relevant pain points.
- Maintain reliable sources and references for the SIH presentation.
- Example: if an existing platform already recommends schemes, identify exactly how our end-to-end journey is different instead of claiming the feature is new.

Vartika — Scheme Intelligence

- Create the structure for storing government schemes and their eligibility conditions.

- Prepare a clean initial dataset for the prototype.
- Build rule-based eligibility checks such as location, income, business type and other scheme-specific criteria.
- Calculate a clear match score and show the reason for the recommendation.
- Example: “78% match — eligible for location and business type; income document still required.”
- Identify alternative schemes when the user is not eligible for the first choice.

Swati — Product + Coordination

- Define the exact features that the team will build.
- Create the end-to-end user flow: profile → scheme discovery → eligibility → application → tracking.
- Write simple requirements for each screen and feature so development teams know what to build.
- Prioritize the 36-hour MVP and remove features that are not essential.
- Track dependencies between members and make sure modules can be integrated.
- Example: decide that unified application tracking is an MVP feature, while advanced analytics can be future scope.

Zain — AI + Innovation

- Design AI features that solve a real user problem rather than adding AI only for presentation.
- Prototype natural-language search. Example: “I want funding for a small manufacturing business in Maharashtra.”
- Convert the user’s sentence into useful fields such as location, business type and requirement, then pass them to the scheme engine.
- Explore semantic search or embeddings as an optional improvement over simple keyword matching.
- Identify innovation opportunities and document why each feature is useful, feasible and different.

Shubhi — Frontend + UI/UX

- Design and build the React web interface.
- Create onboarding, entrepreneur dashboard, scheme results, scheme details, eligibility explanation and application-tracking screens.
- Make the interface responsive and easy to understand.
- Connect the screens to the backend APIs instead of keeping the final product dependent on dummy data.
- Example: when a user clicks “Apply”, the frontend sends the application to the backend and then displays the returned application status.

How the Six Modules Work Together

The project should be developed as connected modules. Each member owns one area, but the interfaces between modules must be agreed before implementation so that integration is straightforward.

Module	Owner	Input	Output
Research	Vanshika	PS + existing systems	Problem gaps, evidence, USP
Product	Swati	Research + team inputs	User flow, requirements, MVP scope
Scheme Engine	Vartika	Scheme data + rules	Eligibility and recommendations
AI	Zain	User queries + scheme data	NLP/semantic search features
Backend	Shivam	Module requirements	APIs, middleware, tracking
Frontend	Shubhi	Product flow + APIs	Working user interface

First Deliverables

- Shivam: backend architecture, API list and interoperability flow.
- Vanshika: existing-solution comparison and evidence-backed problem/USP research.
- Vartika: scheme database structure, initial scheme dataset and eligibility rules.
- Swati: complete user journey, feature list, MVP scope and acceptance criteria.
- Zain: AI feature plan and natural-language search proof of concept.
- Shubhi: screen list, UI structure and first frontend prototype.

MVP Scope Rule

The team should focus on a working prototype rather than attempting to connect every real government portal. Where authorized real APIs are unavailable, use controlled mock or representative service connectors and clearly present them as a demonstration of the interoperability architecture.
